Professional Geologist Certification

The 2011 Semiannual Groundwater Monitoring Report has been prepared under the direction and supervision of a qualified, State of South Carolina licensed, Professional Geologist. Mr. Reinhard Ruhmke, P.G., of Brown and Caldwell was responsible for the overall preparation of the Report.

Juhne

Reinhard Ruhmke, P.G. Managing Geologist South Carolina Professional Geologist #2469

July 29, 2011

Date

Section 1 Introduction

This 2011 Semiannual Groundwater Monitoring Report was prepared by Brown and Caldwell (BC) on behalf of the Owens Corning Starr, South Carolina facility for submittal to the U.S. Environmental Protection Agency (EPA) in accordance with an October 1989 Consent Order (89-34-R) with the EPA under Section 3008(h) of the Resource Recovery and Conservation Act (RCRA). The report summarizes the February and May 2011 quarterly groundwater monitoring events and May 2011 semiannual residential well monitoring event. The Consent Order requires that Owens Corning perform annual groundwater monitoring and in 2005 EPA required that quarterly groundwater monitoring be conducted for select bedrock wells located in the Northeast Area (MW-15, MW-22, and MW-29R). Since that time, additional bedrock monitoring wells (MW-33, MW-35, MW-36, MW-37, MW-38, MW-39, MW-41, and MW-42) have been installed and were included in the two quarterly monitoring events reported herein. In 2009 EPA required Owens Corning to conduct semiannual monitoring of select residential wells located to northeast of the Site.

Section 1 of this report presents an introduction and Section 2 summarizes the groundwater monitoring activities. Section 3 provides and discusses the analytical results and Section 4 provides conclusions. Appendices to this document contain the laboratory analytical reports, historical groundwater data, groundwater sampling field forms, and Mann-Kendall test results.

The Owens Corning facility is situated on 160 acres of land located at 4837 Highway 81 South in Starr, South Carolina within Anderson County (Site). As shown on Figure 1 the property is bounded by Highway 81 South to the west, True Temper Road to the north, Keys Street to the east, and Harry Drive to the south. The facility is located approximately 4 miles south of the town of Anderson.

The facility began its composite systems business operations in 1951 and since then has engaged in the production of glass fiber reinforcements and similar materials for composite systems. Historical manufacturing processes involved a variety of chemicals, including acids and solvents, some of which were inadvertently released to the environment and resulted in significant Site investigation work that has been reported to EPA and the South Carolina Department and Environmental Control (SCDHEC).

Section 2 Groundwater Assessment

Brown and Caldwell personnel performed the first and second quarter groundwater monitoring events between February 14 and 17 and May 9 and 12, 2011, respectively. Residential well sampling was performed on May 10 and 11, 2011. Section 2 provides an overview of these events and includes detailed information on site hydrogeology and aquifer characteristics, groundwater and residential well sampling locations, sampling procedures and analytical methods.

2.1 Subsurface Geology

The Owens Corning site is located within the Inner Piedmont Belt of the Piedmont Geologic Physiographic Province that is characterized by moderate to high-grade metamorphic rocks of Precambrian to early Paleozoic age. The bedrock in the vicinity of the Site is granitic gneiss which is overlain by overburden comprised of clay and silt soil, and saprolite. The saprolite exhibits some structural characteristics of the parent rock material such as foliation and fracturing. The thickness of the overburden and saprolite unit beneath the Site ranges from approximately 5 to 100 feet. The primary lineaments and fracture zones beneath the Site trend in a northeast and southwest orientation (LeGrand and Furcron, 1956). A more detailed description of the geology beneath the Site can be found in the Supplemental RCRA Facility Investigation (RFI) Report (Brown and Caldwell, January 2009), which was prepared by BC on behalf of Owens Corning for submittal to the EPA.

2.2 Aquifer Characteristics

At the Site, groundwater is present in both the overburden/saprolite unit and the bedrock unit. Water level measurements were collected from 31 wells during the February and May 2011 monitoring events. Well construction details, including ground surface and top of casing elevations, are provided in Table 1 and depth to water and groundwater elevations measured during the February and May monitoring events are provided in Tables 2 and 3, respectively. Refer to the Site Map in Figure 1 to identify well locations. This information was used to calculate groundwater elevations and prepare potentiometric maps for the overburden and bedrock aquifers for the February (Figures 2 through 5) and May (Figures 6 through 9) 2011 monitoring events.

Based on the monitoring well measurements from February and May 2011, groundwater levels in the overburden aquifer ranged from approximately 3 (MW-11) to 19 (MW-14) feet below ground surface (bgs) and from 776 to 778 feet in elevation [North American Vertical Datum of 1988 (NAVD88)]. Measurements from the same time period taken from wells in the bedrock aquifer exhibit hydraulic heads ranging from 8 feet above ground surface (MW-41 Zone 2) to 42 feet bgs (MW-42 Zone 2) and from 778 to 743 feet in elevation (NAVD88), with the variation in hydraulic head being highly dependent on both the elevation and fractures present in the wells screened-interval.

Based on the February and May 2011 data, groundwater onsite in both overburden and bedrock aquifers flows toward the fracture zones associated with Betsy Creek, giving an east-northeasterly gradient. Measurements from the bedrock aquifer wells offsite indicate that flow direction continues to align with Betsy Creek as the stream turns to flow to the north-northeast in the area of MW-35. The magnitude of the horizontal gradient onsite varies depending on the aquifer and fracture zone. Based on the May 2011 data, observed horizontal gradients (feet/foot) are as follows: 0.015 in the overburden (calculated between MW-23 and MW-21); 0.015 in the bedrock aquifer in the 699-740 ft NAVD88 zone

Brown AND Caldwell

(calculated between MW-27 and MW-41 Zone 1); 0.015 in the bedrock aquifer in the 660-699 ft NAVD88 zone (calculated between MW-6 and MW-15); and 0.0095 in the bedrock aquifer in the 574-630 ft NAVD88 zone (calculated between MW-19 and MW-41 Zone 2). The following vertical gradients were also observed in May: a downward gradient of 0.0059 onsite near Betsy Creek (calculated between MW-11 and MW-19); and an upward gradient of 0.034 at the intersection of Keys Street and True Temper Road across the overburden/bedrock aquifer (calculated between MW-21 and MW-38 Zone 2).

Additional information can be found in the Supplemental RFI Report (Brown and Caldwell, January 2009).

2.3 Groundwater Monitoring Wells

The original quarterly groundwater monitoring program included seven bedrock monitoring wells (MW-15, MW-22, MW-29R, MW-33, MW-35, MW-36 and MW-37). MW-33 has since been removed from the quarterly and annual groundwater monitoring program because it will become one of the groundwater extraction wells for the interim measures hydraulic containment system. The removal of this well from the monitoring program is of little consequence since there are several wells in the surrounding area that provide both hydraulic potential and concentration data that are used to model plume behavior. During the summer of 2010, four additional bedrock wells (MW-38, MW-39, MW-41, and MW-42) were installed and added to the quarterly monitoring program.

Therefore, the current quarterly groundwater monitoring program includes the following 10 bedrock monitoring wells:

 Bedrock Wells: MW-15, MW-22, MW-29R, MW-35, MW-36, MW-37, MW-38, MW-39, MW-41, and MW-42.

The locations of the wells are shown on Figure 1 and well construction details are provided in Table 1. Multiple water-bearing zones were sampled in bedrock wells MW-29R, MW-36, MW-37, MW-38, MW-39, MW-41, and MW-42 (Tables 4 and 5).

2.4 Groundwater Sampling Procedures

On February 14 and May 9, 2011, depths to groundwater measurements were collected from the 10 bedrock monitoring wells. Water levels were also measured in monitoring wells MW-3, MW-4, MW-6, MW-11, MW-12, MW-13, MW-14, MW-16, MW-19, MW-21, MW-23, MW-25, MW-26, MW-27, P2, Alloy, TW-40, TW-41, TW-42, TW-43 and TW-44. The water level meter was decontaminated between wells with an Alconox® solution and rinsed with distilled water.

Sampling procedures were performed in the same manner as the previous monitoring events. Prior to collecting groundwater samples from the wells, the wells were purged using either a low-flow submersible electric pump, bladder pump or a peristaltic pump. The Waterloo system monitoring zones were purged and sampled using their dedicated compressed air driven stainless steel double valve pumps. Groundwater was pumped at an approximate rate of 0.25 gallons per minute through new or dedicated polyethylene tubing equipped with a field-calibrated, in-line YSI® 556 meter to measure field parameters: pH, temperature, specific conductance, oxidation-reduction potential (ORP), and dissolved oxygen (DO). Turbidity was measured using a HF® Scientific DRT-15CE turbidity meter. Purging was considered complete when at least three of the field parameters had stabilized. An attempt was made to obtain turbidity readings of less than 10 Nephelometric Turbidity Units (NTUs); however, this was not achieved for all the wells. Groundwater samples were collected when pH, temperature and specific conductance had stabilized as defined in EPA's Environmental Investigations Standard Operating Procedures and Quality Assurance Manual (EISOP/QAM), November 2001 and Science and EPA's Ecosystem Support Division Groundwater Sampling Procedure (SESDPROC-301-RO), February 2007. Groundwater sampling field data sheets documenting the purging activities are included as Appendix A.

Groundwater samples were collected from the wells using the same low-flow pump that was used for purging. The pump was decontaminated between sample locations using an Alconox® solution and rinsed with distilled water. The groundwater samples were labeled, containerized, documented, placed into a cooler containing ice and chilled to about 4 degrees Celsius (temperatures verified by laboratory and are reported in the laboratory analytical report in Appendix B). Monitoring wells were sampled from least contaminated to most contaminated, based on previous groundwater monitoring data, to minimize the potential for carryover and cross-contamination between wells.

2.5 Residential Well Sampling Procedures

During the May 2011 quarterly sampling event, 12 residential wells were sampled (Figure 10). Two additional residences were visited but their wells could not be sampled; the groundwater pump in the well at 134 Friendship Lane was disconnected, and there was insufficient groundwater in the well at 335 Elrod Road to collect a sample.

The residential wells were sampled in accordance with methods described in EPA's Field Branches Quality System and Technical Procedures. Wells that pumped into a holding tank were purged of at least one tank volume (generally 15 to 20 gallons) and water quality parameters such as, pH, conductivity, temperature, DO, ORP, and turbidity were measured and recorded in a field notebook. After purging, the samples were collected at a low flow rate through a hose connected to the holding tank. Wells that did not utilize a holding tank were sampled directly from the well head. The groundwater samples were labeled, containerized, documented, placed into a cooler containing ice and chilled to about 4 degrees Celsius (temperatures verified by laboratory and are reported in the laboratory analytical report in Appendix B).

Once the analytical data were validated, a letter documenting the results for each well owner was prepared and delivered to each well owner by Mr. Steve Tenry, the Anderson Plant Environmental Manager.

2.6 Analytical Procedures

Groundwater and residential well samples were submitted to Analytical Environmental Services, Inc. (AES) of Atlanta, Georgia for analysis of the focused list of volatile organic compounds (VOCs) using EPA Method 8260B. The focused list of VOCs included tetrachloroethene (PCE); trichloroethene (TCE); 1,1,1-trichloroethane (1,1,1-TCA); 1,1-dichloroethane (1,1-DCA); 1,2-dichloroethane (1,2-DCA); 1,1-dichloroethene (cis-1,2-DCE); trans-1,2-dichloroethene (trans-1,2-DCE); vinyl chloride; carbon tetrachloride; chloroform; methylene chloride; benzene; toluene; ethylbenzene and xylenes.

2.7 Quality Assurance/Quality Control

The groundwater sampling was performed in accordance with EPA's EISOP/QAM, November 2001 and EPA's SESDPROC-301-RO. To assess the quality of the sampling program, duplicate samples were collected (approximately one sample for every 20 samples) and analyzed for the focused list of VOCs. One duplicate sample was collected during the February sampling event. One duplicate groundwater sample and one duplicate residential well sample were collected during the May sampling event. An evaluation of the analytical results for the duplicate samples showed that the reported constituents and concentrations were similar. Three equipment blanks (EBs) were collected during the February sampling and four EBs were collected during the May sampling to determine the efficacy of non-dedicated equipment decontamination activities. The EB samples were obtained by collecting distilled water passed through or over decontaminated equipment. Trip blanks, provided by AES, were in all coolers and were submitted for analysis with the groundwater samples. The EB and trip blank samples were analyzed for the same constituents as the groundwater samples. No detections were found in any of the EB or trip blank samples. The analytical reports for these samples are provided in Appendix B.

Brown AND Caldwell

Section 3 Analytical Results

The following section includes the results for the February and May 2011 quarterly groundwater events and the May 2011 residential well monitoring event. The quarterly events included collecting groundwater samples from six bedrock wells located on the northeast portion of the Owens Corning property (including MW-15, MW-22, MW-29R, MW-36, MW-37, and MW-38), and four offsite bedrock wells (MW-35, MW-39, MW-41, and MW-42). In addition, samples were collected from 12 residential wells during the May 2011 quarterly event.

The February and May 2011 groundwater analytical results are summarized in Tables 4 and 5, respectively. The May 2011 residential well analytical results are summarized in Table 6. Historical groundwater analytical data can be found in previous reports submitted to EPA and summaries of this information can be found in Appendix C of this report. Analytical reports that include method detection limits and quality assurance/quality control (QA/QC) information are provided in Appendix B.

One analytical parameter, 1,1-DCE, was selected for presentation on isoconcentration contour maps for the February and May events as shown on Figures 11 through 16. This analyte was selected because it is the most prevalent and widespread analyte detected in the bedrock wells.

3.1 Groundwater Analytical Results

To understand the distribution of 1,1-DCE, isoconcentration maps were created for multiple vertical intervals within the fractured bedrock. The projected distribution of 1,1-DCE over the vertical intervals from 699 feet to 740 feet, 660 feet to 699 feet and 574 feet to 630 feet NAVD88 for the February and May 2011 events is presented on Figures 11 through 13 and Figures 14 through 16, respectively. Assuming that 1,1-DCE entered the top of bedrock near solid waste management unit (SWMU) 9, the axis of the plume, consistent with the groundwater flow direction and local bedrock fracture patterns as identified in the Bedrock Geologic Map of the Little Mountain Area Anderson South Quadrangle, is oriented to the north-northeast. Refer to the *Supplemental RCRA Facility Investigation Report* (Brown and Caldwell, January 2009) for a more detailed review of these figures.

Concentrations of 1,1-DCE in wells MW-15 and MW-22 have both decreased since February 2009 (Tables 4 and 5). MW-22 is located just northeast of the wastewater lagoons. The concentration of 1,1-DCE in MW-22 decreased from 570 microgram per liter (ug/L) in February to 310 ug/L in May 2011. In MW-15, located northeast of MW-22, 1,1-DCE remained relatively stable from February and May 2011, with concentrations of 260 and 250 ug/L, respectively.

Concentrations of 1,1-DCE in well MW-29R Zone 3 and Zone 4 appear to be consistent with historical values. In Zone 3, the concentration of 1,1-DCE was 340 ug/L in February which increased to 560 ug/L in May 2011, following a similar trend shown in 2010. In Zone 4, concentrations followed a very similar trend as Zone 3 and as shown in 2010, starting the year at 320 ug/L in February and increasing to 590 ug/L in May. In well MW-36, located north and hydraulically downgradient of well MW-29R, 1,1-DCE has not been detected above its' groundwater maximum contaminant level (MCL) of 7 ug/L in any of the three zones since it was installed in 2008.

During the first two quarterly monitoring events of 2011, the concentration of 1,1-DCE in MW-37 Zone 1 decreased from 40 μ g/L in February to 9.7 μ g/L in May. Concentrations of 1,1-DCE in MW-37 Zone 2 increased from 97 μ g/L in February to 190 μ g/L in May. Concentrations of 1,1-DCE concentrations in MW-37 Zone 3 have decreased since 2009. In Zone 3, the concentration of 1,1-DCE was < 5 μ g/L in both the February and May 2011 quarterly sampling events, compared to 11 ug/L back in February 2009. Bedrock well MW-39 was installed in summer 2010 southeast of MW-37 to delineate 1,1-DCE in this direction. No VOCs, including 1,1-DCE, were detected in groundwater from MW-39 above laboratory reporting limits (RLs) during the February and May monitoring events (Tables 4 and 5). Accordingly, delineation of the south edge of the plume appears to be complete.

Well MW-35, an artesian well located northeast of the intersection of True Temper Road and Keys Streets, contained 290 µg/L of 1,1-DCE in February, a decrease from 490 ug/L that was measured in November 2010. However, the concentration of 1,1-DCE in MW-35 increased to 530 ug/L in May. Overall, however, concentrations of 1,1-DCE in MW-35 appear to be consistent with historical values. Bedrock wells MW-41 and MW-42 were first included in the monitoring program in summer of 2010 to delineate 1,1-DCE in the Northeast Area. Both wells consist of nested wells, such that three independent zones could be sampled. The 1,1-DCE concentration in MW-41 Zone 1 increased from 380 ug/L in February to 450 ug/L in May 2011. Zone 2 contained 350 ug/L of 1,1-DCE during the February monitoring event and 250 ug/L during the May monitoring event. Groundwater collected from MW-41 Zone 3 contained 150 ug/L of 1,1-DCE in February and 96 ug/L in May 2011, compared to 260 ug/L originally measured in August 2010. MW-42 is currently the farthest well from the Site in the hydraulically downgradient northeast direction. During the February and May monitoring events, no VOCs were detected above MCLs in groundwater collected from MW-42. Therefore, the plume appears to be delineated to the northeast.

The only other contaminant detected above an MCL in the bedrock wells was carbon tetrachloride. This contaminant was detected in MW-22 and MW-29R Zones 3 and 4 during both monitoring events at maximum concentrations of 19 μ g/L in February (MW-22) and 23 ug/L in May (MW-22 and MW-29R). No other parameters from the focused list of VOCs were detected above MCLs in the bedrock well samples.

3.2 Residential Well Analytical Results

None of the parameters from the focused list of VOCs were detected above RLs in the residential well samples. All residential well analytical results are included in Table 6. Approximate locations of the residential wells are depicted on Figure 10, with the corresponding well location map ID's provided in Table 7. Analytical reports that include method detection limits and QA/QC information are provided in Appendix B.

Section 4 Summary and Conclusions

The first and second quarterly monitoring events were conducted at the Owens Corning Site in February and May 2011, respectively. Samples were collected from 10 bedrock wells during the each of the quarterly sampling events and from 12 residential wells during the May sampling event. The samples were analyzed for the focused list of VOCs. Multiple water-bearing zones were sampled in wells MW-29R, MW-36, MW-37, MW-38, MW-39, MW-41, and MW-42.

The following conclusions were developed based on the quarterly monitoring events summarized in this report:

- Based on historical and recent site monitoring data 1,1-DCE and 1,1,1-TCA are the primary constituents in groundwater, though 1,1 DCE is the primary constituent that persists beyond SWMU-9 and the property boundary, though there it is only found within the bedrock water-bearing zone and not the overburden.
- The main constituent in the bedrock aquifer is 1,1-DCE. Concentration data obtained from the Northeast Area bedrock wells MW-29R, MW-35 and MW-37 reveal that the plume in this area has been relatively stable since early 2010. The only other VOC detected in bedrock wells above an MCL was carbon tetrachloride at concentrations less than 25 ug/L since early 2010.
- In bedrock well MW-41, located downgradient and to the north of MW-35, the concentration of 1,1-DCE has decreased in Zone 3 since the August 2010 monitoring event by 63 percent. Concentrations of 1,1-DCE in Zones 1 and 2 have remained relatively consistent in this well.
- 1,1-DCE and carbon tetrachloride concentrations in the bedrock wells appear to be consistent with or less than recent historical values.
- During the February and May 2011 monitoring events, no VOCs were detected above MCLs in groundwater collected from the offsite bedrock wells, MW-39 and MW-42. Monitoring well MW-42 is the farthest monitoring well in the northeast direction from the Site, and monitoring well MW-39 is the farthest in the southeast direction. Accordingly, delineation of the south and eastern edges of the plume appears to be complete.
- Owens Corning previously proposed the installation of another bedrock well downgradient of MW-41 for additional delineation of the VOC plume. Monitoring well MW-43 with three independent monitoring zones was therefore installed in April 2011. Packer testing was completed and no VOCs were detected above MCLs in groundwater collected from the three zones. Accordingly, delineation to the north appears to be complete.

The next quarterly monitoring event is planned for August 2011, followed by the annual monitoring event in November 2011.

Section 5 Limitations

This document was prepared solely for Owens Corning in accordance with professional standards at the time the services were performed and in accordance with the contract between Owens Corning and Brown and Caldwell dated January 11, 2011. This document is governed by the specific scope of work authorized by Owens Corning; it is not intended to be relied upon by any other party except for regulatory authorities contemplated by the scope of work. We have relied on information or instructions provided by Owens Corning and other parties and, unless otherwise expressly indicated, have made no independent investigation as to the validity, completeness, or accuracy of such information.

BR - Bedrock; O - Overburden; TOR - Top of Rock

BGS - Below Ground Surface; TOC - Top of Casing

NG - Not Gauged

MW-41 Zone 2, MW-38 Zone 2 TOC elevation has been adjusted by adding couplings and ball valve to surveyed

DTW readings at artesian wells were measured by attaching pressure gauge to top of ball valve, these values are indicated by the "-" before the measured value.

NAVD88 - North American Vertical Datum of 1988

BR - Bedrock; O - Overburden; TOR - Top of Rock

BGS - Below Ground Surface; TOC - Top of Casing

NG - Not Gauged

MW-41 Zone 2, MW-38 Zone 2 TOC elevation has been adjusted by adding couplings and ball valve to surveyed

DTW readings at artesian wells were measured by attaching pressure gauge to top of ball valve, these values are indicated by the "-" before the measured value.

NAVD88 - North American Vertical Datum of 1988

†Duplicate sample Dup-021711 was collected from MW-42 Zone 1.

<sup>1</sup> MCL listed for Chloroform is for Total Trihalomethanes. MCL - Maximum Contaminant Level

Bold VOC results indicates concentration above the MCL.

NA - Not Applicable

\* Duplicate sample Dup-051011 was collected from 303 Kaye Dr.

<sup>1</sup> MCL listed for Chloroform is for Total Trihalomethanes. MCL - Maximum Contaminant Level

NS - Not sampled; Pump is disconnected

Dry - Not enough water in well to sample

**Bold** VOC results indicates concentration above the MCL.

NA - Not Applicable
